MCM2MCMC USER MANUAL: SOFTWARE IMPLEMENTING A MARKOV CHAIN MONTE CARLO ALGORITHM FOR UNCERTAINTY EVALUATION BASED ON THE MONTE CARLO METHOD OF SUPPLEMENT 1 TO THE GUM

A B FORBES, K JAGAN AND I M SMITH

APRIL 2018
ABSTRACT

This report constitutes a user manual for software developed at the National Physical Laboratory to convert a sample from a Bayesian posterior distribution corresponding to a particular choice of prior distribution derived using the Monte Carlo method, to a Bayesian posterior corresponding to a preferred prior distribution. A Metropolis-Hastings Markov chain Monte Carlo algorithm is used to achieve this conversion.

1 Introduction

1.1 Scope

This document describes MATLAB software implementing the second stage of a two-stage algorithm for uncertainty evaluation described in [6, 7]. The first stage uses the Monte Carlo method (MCM) [2, 3, 4] to produce a sample from a probability distribution that can be regarded as a Bayesian posterior distribution corresponding to a particular choice of prior distribution imposed by the computational approach. The second stage uses a Metropolis-Hastings Markov chain Monte Carlo (MCMC) algorithm to convert the MCM sample to a sample from the Bayesian posterior distribution corresponding to a preferred prior distribution. Section 2 describes the model underlying the algorithm, Section 3 describes the individual software components and numerical examples are given in Section 4.

1.2 Software user licence agreement

The software is provided with a software user licence agreement and the use of the software is subject to the terms laid out in that agreement. By running the software, the user accepts the terms of the agreement.

2 Measurement response model

The software is concerned with the case in which the responses \( \eta = (\eta_1, \ldots, \eta_k)^\top \) of an instrument are modelled as functions of influence quantities \( \beta = (\beta_1, \ldots, \beta_m)^\top \) and quantities of interest \( \alpha = (\alpha_1, \ldots, \alpha_k)^\top \).

The instrument response \( \eta_i \) is modelled as

\[
\eta_i = \phi_i(\alpha, \beta), \quad i = 1, \ldots, k,
\]

so that

\[
\eta = \begin{bmatrix}
\eta_1 \\
\vdots \\
\eta_k
\end{bmatrix} = \begin{bmatrix}
\phi_1(\alpha, \beta) \\
\vdots \\
\phi_k(\alpha, \beta)
\end{bmatrix} = \phi(\alpha, \beta).
\]

It is assumed that the response model can be re-expressed as

\[
\alpha = \begin{bmatrix}
\alpha_1 \\
\vdots \\
\alpha_k
\end{bmatrix} = \begin{bmatrix}
\psi_1(\eta, \beta) \\
\vdots \\
\psi_k(\eta, \beta)
\end{bmatrix} = \psi(\eta, \beta), \tag{1}
\]
expressing $\alpha$ as an explicit function of $\eta$ and $\beta$.

A joint probability density $p(\eta, \beta)$ for $\eta$ and $\beta$ may be propagated through model (1) to $p(\alpha)$ for $\alpha$ using a Monte Carlo method. If $\{(y_q, b_q), \ q = 1, \ldots, M\}$ is a sample drawn from $p(\eta, \beta)$, then $\{a_q = \psi(y_q, b_q), \ q = 1, \ldots, M\}$ is a sample from $p(\alpha)$.

Supplement 1 (GUMS1, [2]) and Supplement 2 (GUMS2, [3]) to the Guide to the expression of uncertainty in measurement (GUM, [1]) employ the Monte Carlo method in the following context. It is assumed that prior knowledge about the influence quantities is encoded in a prior density $p(\beta)$. Measurement of the response of the instrument produces indications $\zeta$ with associated likelihood $p(\zeta | \eta) \equiv p(\zeta | \alpha, \beta)$, e.g.,

$$\zeta | \eta \sim N(\eta, \sigma^2 I).$$

On the basis of $\zeta$, $\eta$ is assigned a density $p(\eta | \zeta) \propto p(\zeta | \eta)$, i.e., the Bayesian posterior distribution corresponding to a non-informative prior $p(\eta) \propto 1$ for $\eta$. For this example, the form of the density $p(\eta | \zeta)$ is

$$p(\eta | \zeta) \propto \frac{1}{\sigma} \exp \left\{ -\frac{1}{2\sigma^2} (\zeta - \eta)^\top (\zeta - \eta) \right\}.$$

The joint density $p(\eta, \beta | \zeta)$ is assigned to be

$$p(\eta, \beta | \zeta) = p(\eta | \zeta)p(\beta),$$

and independent samples $\{y_q, q = 1, \ldots, M\}$ and $\{b_q, q = 1, \ldots, M\}$ are drawn from $p(\eta | \zeta)$ and $p(\beta)$, respectively. It can be shown [5, 8] that $\{(a_q, b_q), \ q = 1, \ldots, M\}$, with $a_q = \psi(y_q, b_q)$, are draws from the Bayesian posterior distribution

$$p_{\text{MCM}}(\alpha, \beta | \zeta) \propto p(\zeta | \alpha, \beta) |J(\alpha, \beta)| p(\beta),$$

where $|J(\alpha, \beta)|$ is the absolute value of the determinant of the Jacobian matrix $J = J(\alpha, \beta)$ with

$$J_{ij} = \frac{\partial \phi_i}{\partial \alpha_j}(\alpha, \beta).$$

Thus, the MCM approach provides a sample from a Bayesian posterior distribution corresponding to the prior

$$p(\alpha, \beta) \propto |J(\alpha, \beta)| p(\beta).$$

If the preferred prior is $p(\alpha, \beta) = p_{00}(\alpha)p(\beta)$, leading to posterior distribution

$$p(\alpha, \beta | \zeta) \propto p(\zeta | \alpha, \beta)p_{00}(\alpha)p(\beta),$$

then

$$\frac{p(\alpha, \beta | \zeta)}{p_{\text{MCM}}(\alpha, \beta | \zeta)} \propto \frac{p_{00}(\alpha)}{|J(\alpha, \beta)|}.$$ (2)
involving only \( p_0(\alpha) \) and \(|J(\alpha, \beta)|\). For the case of a univariate response model, 
\[ \eta = \phi(\alpha, \beta), \]
\( \alpha \) and \( J \) are scalar quantities, where 
\[ J = \frac{\partial \phi}{\partial \alpha}(\alpha, \beta). \]

The relationship (2) leads to a particularly simple implementation of the Metropolis-Hastings independence chain algorithm \([9, 10]\) in which draws from the approximating distribution \( p_{MCM}(\alpha, \beta|\zeta) \) are converted to draws from \( p(\alpha, \beta|\zeta) \).

3 Software implementation

3.1 Metropolis-Hastings independence chain algorithm

The Metropolis-Hastings independence chain (MHIC) algorithm determines a sample from a target distribution \( p(\alpha) \) given a sample from an approximating distribution \( p_0(\alpha) \). The algorithm assumes that \( \{a_{0,q,r}, q = 1, \ldots, M, r = 1, \ldots, N\} \) have been sampled independently from \( p_0(\alpha) \) and that densities \( p_0(a_{0,q,r}) \) and \( p(a_{0,q,r}) \) have been evaluated, each up to a normalising constant. The algorithm requires that each chain starts at a feasible point, i.e., \( p(a_{0,0,r}) > 0 \) for all \( r \). Since the sample \( a_{0,q,r} \) has been drawn, necessarily \( p_0(a_{0,q,r}) > 0 \). With this information, \( N \) chains of length \( M \) are determined, \( \{a_{q,r}, q = 1, \ldots, M, r = 1, \ldots, N\} \), accepting or rejecting the proposed \( a_{0,q,r} \), according to the Metropolis-Hastings scheme (see, e.g., \([10]\)).

The MHIC algorithm can be applied in situations in which samples are required from a distribution \( p(\alpha) \) which has an approximating distribution \( p_0(\alpha) \) that is easy to sample from. The general procedure is outlined below.

Given a draw \( a_{q-1} \), a proposed draw \( a^* \) for the next member of the sequence is sampled at random from the approximating distribution \( p_0(\alpha) \). Then \( a_q \) is set to \( a^* \) with acceptance probability 
\[ p_q = \min\{1, r_q\}, \quad r_q = \frac{p(a^*)p_0(a_{q-1})}{p(a_{q-1})p_0(a^*)}. \]

A number of iterations are allowed for the Markov chain to reach the target distribution. This number is known as the “burn-in period”. A burn-in period of length \( M_0 \) is assigned, with the intention that, for \( q > M_0 \), \( a_q \) is assumed to be a sample from the posterior distribution.

For the current problem, the MCM sample of \( \alpha \) and \( \beta \) is considered to be a sample from the approximating distribution and the target distribution is the joint posterior distribution for \( \alpha \) and \( \beta \) with a preferred prior for \( \alpha \).
The MHIC algorithm is implemented in two software components:

- `mhicI.m`: Use \( p_0(a_{0,q,r}) \) and \( p(a_{0,q,r}) \) to evaluate indices that determine which samples are accepted and which are rejected.
- `mhic2a.m`: Use the indices to convert the sample \( a_{0,q,r} \) to a sample \( a_{q,r} \) from the posterior distribution, \( q > M_0 \).

Two further software components are also provided:

- `mcmcci.m`: Assess the convergence of an MCMC algorithm from multiple chains.
- `mcmcsum.m`: Provide summary information about the posterior distribution on the basis of the sample \( a_{q,r} \).

The first three software components apply to a single (scalar) quantity, whereas the last component applies to a general (vector) quantity.

### 3.1.1 Determine selection indices

The software component `mhicI.m` has calling syntax

\[ [IS, IA] = mhicI(P, P0) \]

Given \( p \) and \( p_0 \) evaluated at an \( M \times N \) array of samples \( a_{0,q,r} \), this component calculates the selection indices \( I_S \) used to convert the samples to Markov chains, and the acceptance indices \( I_A \).

<table>

</tr>
</tbody>
</table>
3.1.2 Apply selection indices

The software component `mhicia2a.m` has calling syntax

\[ [A] = mhicia2a(A0, IS) \]

This component uses the selection indices \( IS \) to convert the samples contained in \( A_0 \) to Markov chains.

<table>
<thead>
<tr>

</tbody>
</table>
3.1.3 Determine convergence indices

The software component `mcmcci.m` has calling syntax

\[ [\hat{R}, n_{\text{eff}}, \bar{a}, s] = \text{mcmcci}(A, M_0) \]

This component may be applied to the outputs of any MCMC scheme involving multiple chains. It evaluates convergence indices that indicate if the chains have converged to the target distribution based on the scheme described in [10, Section 11.4].

<table>
<thead>
<tr>

</tr>
<tr>
<td>(s)</td>
<td>(M \times 1)</td>
<td>Vector storing the standard deviations (s_q) of the rows (A_{q,r}, r = 1, \ldots, N), of the array (A).</td>
</tr>
</tbody>
</table>
3.1.4 Calculate sample summary information

The software component `mcmcsum.m` has calling syntax

\[ [\text{abar}, s, aQ, V, AA] = \text{mcmcsum}(A, M0, Q) \]

This component may be applied to the outputs of any MCMC scheme (or indeed any sampling scheme). It provides estimates of quantiles derived from the samples associated with the quantities. Here, \( A \) contains the samples for a vector quantity and is of dimension \( M \times N \times L \). For the case where the vector quantity comprises \( \alpha \) and \( \beta \), \( L = k + m \).

Given \( 0 \leq q \leq 100 \), the associated quantile \( Q \) is such that

\[ \Pr(\alpha \leq Q) = q/100. \]

If \( q = 0 \), the component calculates the minimum of the sample; if \( q = 100 \), the component calculates the maximum of the sample.

<table>
<thead>

</tbody>
</table>
3.2 MHIC applied to uncertainty evaluation

The software component `mcm2mcmc.m` has calling syntax

```matlab
[A,Rhat,Neff,IS,IA] = mcm2mcmc(A0,D,M0,P00)
```

This component generates Markov chains associated with the target distribution \( p(\alpha, \beta | \zeta) \) given a sample from the distribution \( p_{MCM}(\alpha, \beta | \zeta) \). The samples are generated as follows. For \( q = 1, \ldots, M, \) and \( r = 1, \ldots, N \), sample \( y_{q,r} \) according to \( p(\eta | \zeta) \) and \( b_{q,r} \) according to \( p(\beta) \) and evaluate

\[
a_{0,q,r} = \psi(y_{q,r}, b_{q,r}), \quad D_{q,r} = |J(a_{0,q,r}, b_{q,r})|, \quad P_{00,q,r} = p_{00}(a_{q,r}).
\]

For univariate models (as covered by GUMS1), \( D(q,r) \) stores

\[
D_{q,r} = \left| \frac{\partial \phi}{\partial \alpha} (a_{0,q,r}, b_{q,r}) \right|.
\]

The samples corresponding to quantities \( \alpha \) and \( \beta \) are stored in \( L = k + m \) arrays of dimension \( M \times N \).

`mcm2mcmc.m` calls modules `mhicI.m`, `mhicia2a.m` and `mcmcci.m`.

4 Numerical examples

4.1 Gauge block examples

The gauge block examples involve the observation and measurement models

\[
\eta = \phi(\alpha, \beta_1, \beta_2) = \alpha [1 + \beta_2(\beta_1 - b_1)], \quad \alpha = \psi(\eta, \beta_1, \beta_2) = \frac{\eta}{1 + \beta_2(\beta_1 - b_1)},
\]

where \( \eta \) is the length (mm) of the gauge block at temperature \( \beta_1 (\degree C) \), \( \alpha \) is the length (mm) of the gauge block at the reference temperature \( b_1 = 20 \degree C \), and \( \beta_2 \) is the coefficient of thermal expansion (\( \degree C^{-1} \)).

Rectangular priors are assigned to \( \beta_1 \) and \( \beta_2 \):

\[
\beta_1 \sim R(18, 22), \quad \beta_2 \sim R(0.09, 0.11).
\]

A non-informative prior is assumed for \( \alpha \), \( p_{00}(\alpha) \propto 1 \).

Three examples are considered:

1. Likelihood specified by a Gaussian distribution (Section 4.1.1)
2. Likelihood defined by a Student’s t distribution (Section 4.1.2)
3. Likelihood specified by a symmetric Beta distribution (Section 4.1.3)

These examples illustrate that the algorithm is applicable to a range of likelihood functions and is not restricted to the Gaussian case alone. In particular, the Student’s t likelihood indicates that \( \zeta \) is derived from repeated measurements, and the symmetric Beta likelihood indicates that \( \zeta \) has a distribution that is symmetric but is finite in extent.

Figure 1 shows the shapes of the likelihoods \( p(\zeta | \eta) \) for each of the three cases.
Figure 1: Sampling distributions for $\zeta | \eta$. 
4.1.1 Example 1: Likelihood defined by a Gaussian distribution

The likelihood of observing $\zeta$, given $\eta$, is specified by

$$\zeta | \eta \sim N(\eta, \sigma^2).$$

An indication $\zeta = 100$ is observed, with $\sigma$ taken to be 2, so that $\eta | \zeta$ is assigned the distribution

$$\eta | \zeta \sim N(100, 2^2).$$

The MCM approach samples $b_{1,q,r} \in R(18, 22), \ b_{2,q,r} \in R(0.09, 0.11)$ and $y_{q,r} \in N(100, 2^2)$, and evaluates

$$a_{0,q,r} = \frac{y_{q,r}}{1 + b_{2,q,r}(b_{1,q,r} - b_1)}.$$

In order to implement the MCMC algorithm, it is also required to evaluate

$$D(q, r) = \left| \frac{\partial \phi}{\partial \alpha}(a_{0,q,r}, b_{1,q,r}, b_{2,q,r}) \right| = |1 + b_{2,q,r}(b_{1,q,r} - b_1)|.$$

The array $A_0$ is of dimension $M \times N \times 3$, comprising $N$ chains of length $M$ for each of the three quantities $\alpha, \beta_1$ and $\beta_2$.

The calculations are performed in r_gauge_block_example_1.m and the results are published in r_gauge_block_example_1.html. Convergence indices along with the summary statistics based on the posterior distribution are displayed below.

Figure 2: Posterior distributions estimated from MCM and MCMC samples for gauge block example 1.
4.1.2 Example 2: Likelihood defined by a Student’s t-distribution

The likelihood of observing $\zeta$, given $\eta$, is specified by

$$\zeta | \eta \sim t_\nu (\eta, s^2).$$

An indication $\zeta = 100$ is observed, and $s$ and $\nu$ are taken to be 2 and 5, respectively, so that $\eta | \zeta$ is assigned the distribution

$$\eta | \zeta \sim t_5 (100, 2^2).$$

The MCM approach samples

$$b_{1,q,r} \in \mathbb{R}(18, 22), \quad b_{2,q,r} \in \mathbb{R}(0.09, 0.11) \quad \text{and} \quad y_{q,r} \in t_5 (100, 2^2),$$

and evaluates

$$a_{0,q,r} = \frac{y_{q,r}}{1 + b_{2,q,r} (b_{1,q,r} - b_1)}.$$

In order to implement the MCMC algorithm, it is also required to evaluate

$$D(q, r) = |1 + b_{2,q,r} (b_{1,q,r} - b_1)|.$$

The array $A_0$ is of dimension $M \times N \times 3$, comprising $N$ chains of length $M$ for each of the three quantities $\alpha$, $\beta_1$ and $\beta_2$.

The calculations are performed in \texttt{r.gauge_block_example_2.m} and the results are published in \texttt{r.gauge_block_example_2.html}. Convergence indices along with the summary statistics based on the posterior distribution are displayed below.

Figure 3 shows the posterior distributions for $\alpha$, $\beta_1$ and $\beta_2$ estimated from the MCM and MCMC samples.
Figure 3: Posterior distributions estimated from MCM and MCMC samples for gauge block example 2.
4.1.3 Example 3: Likelihood specified by a symmetric Beta distribution

The likelihood of observing $\zeta$, given $\eta$, is specified by

$$\zeta|\eta \sim \text{Beta}(\eta - \kappa, \eta + \kappa, p_S, p_S),$$

where $\text{Beta}(\eta - \kappa, \eta + \kappa, p_S, p_S)$ is the symmetric standard Beta distribution defined by shape parameters $p_{S,1} = p_S$ and $p_{S,2} = p_S$, shifted and scaled such that it is non-zero only on the interval $(\eta - \kappa, \eta + \kappa)$. The value $\kappa = \sigma(2p_S + 1)^{1/2}$ is chosen so that the standard deviation of the distribution is $\sigma$.

An indication $\zeta = 100$ is observed, and $\sigma$ and $p_S$ are taken to be 2 and 5, respectively, so that $\eta|\zeta$ is assigned the distribution

$$\eta|\zeta \sim \text{Beta}(100 - \kappa, 100 + \kappa, 5, 5),$$

where $\kappa = 2\sqrt{11}$. The MCM approach samples $b_{1,q,r} \in \mathbb{R}(18, 22), \quad b_{2,q,r} \in \mathbb{R}(0.09, 0.11)$ and $y_{q,r} \in \text{Beta}(100 - \kappa, 100 + \kappa, 5, 5)$, and evaluates

$$a_{0,q,r} = \frac{y_{q,r}}{1 + b_{2,q,r}(b_{1,q,r} - b_1)}.$$

In order to implement the MCMC algorithm, it is also required to evaluate

$$D(q,r) = |1 + b_{2,q,r}(b_{1,q,r} - b_1)|.$$

The array $A_0$ is of dimension $M \times N \times 3$, comprising $N$ chains of length $M$ for each of the three quantities $\alpha, \beta_1$ and $\beta_2$.

The calculations are performed in `r_gauge_block_example_3.m` and the results are published in `r_gauge_block_example_3.html`. Convergence indices along with the summary statistics based on the posterior distribution are displayed below.

Figure 4 shows the posterior distributions for $\alpha$, $\beta_1$ and $\beta_2$ estimated from the MCM and MCMC samples.
Figure 4: Posterior distributions estimated from MCM and MCMC samples for gauge block example 3.
4.2 Exponential examples

Two examples are considered:

1. A univariate model (Section 4.2.1)
2. A bivariate model (Section 4.2.2)

See also [6].

4.2.1 Example 1: Univariate problem

These calculations involve the response model

\[ \eta = \phi(\alpha, \beta) = \alpha e^{-\beta}, \quad \zeta|\eta \sim N(\eta, \sigma^2), \quad \beta \sim N(b, \sigma_B^2), \]

for the case \( b = 2, \sigma = 0.2, \sigma_B = 0.2 \) and \( \zeta = 50e^{-b} \). On this basis, \( \eta|\zeta \) is assigned the distribution

\[ \eta|\zeta \sim N(\zeta, \sigma^2). \]

A non-informative prior is assumed for \( \alpha \).

Given draws \( y_{q,r} \in N(\zeta, \sigma^2) \) and \( b_{q,r} \in N(b, \sigma_B^2) \), assign

\[ a_{0,q,r} = y_{q,r} \exp(b_{q,r}), \quad D(q, r) = \exp(-b_{q,r}). \]

The array \( A_0 \) is of dimension \( M \times N \times 2 \), comprising \( N \) chains of length \( M \) for each of the two quantities \( \alpha \) and \( \beta \).

The calculations are performed in \texttt{r_exponential_example1.m} and the results are published in \texttt{r_exponential_example1.html}. Convergence indices along with the summary statistics based on the posterior distribution are displayed below.

Figure 5 shows the posterior distributions for \( \alpha \) and \( \beta \) estimated from the MCM and MCMC samples.
Figure 5: Posterior distributions estimated from MCM and MCMC samples for exponential example 1.
4.2.2 Example 2: Bivariate problem

These calculations involve the response model
\[
\eta_1 = \phi_1(\alpha, \beta) = \alpha e^{-\beta}, \quad \zeta_1 | \eta_1 \sim N(\eta_1, \sigma_1^2),
\]
\[
\eta_2 = \phi_2(\alpha, \beta) = (\alpha + \alpha_2) e^{-\beta}, \quad \zeta_2 | \eta_2 \sim N(\eta_2, \sigma_2^2),
\]
where \( \beta \sim N(b, \sigma_B^2) \), and there is a prior constraint that \( \alpha_2 \geq 0 \). This model corresponds, for example, to measuring a background response \( \eta_1 \) and a response \( \eta_2 \) involving an additional source \( \alpha_2 \) that is necessarily non-negative.

The Jacobian matrix \( J \) of partial derivatives with respect to \( \alpha_1 \) and \( \alpha_2 \) and its determinant \( |J| \) are given by
\[
J = \begin{bmatrix}
e^{-\beta} & 0 \\
e^{-\beta} & e^{-\beta}
\end{bmatrix}, \quad |J| = e^{-2\beta}.
\]

Given draws \( y_{1,q,r} \in N(\zeta_1, \sigma^2), y_{2,q,r} \in N(\zeta_2, \sigma^2) \) and \( b_{q,r} \in N(b, \sigma_B^2) \), assign
\[
a_{1,0,q,r} = y_{1,q,r} \exp(b_{q,r}), \quad a_{2,0,q,r} = (y_{2,q,r} - y_{1,q,r}) \exp(b_{q,r}), \quad D(q,r) = \exp(-2b_{q,r}),
\]
and \( P_{00}(q,r) = 1 \) if \( a_{2,0,q,r} \geq 0 \), and equal to zero otherwise. Some adjustment to the samples may be required to ensure that \( a_{2,0,1,r} > 0 \) for all \( r \) so that \( P_{00}(1,r) > 0 \) as required by the MHIC algorithm. The array \( A_0 \) is of dimension \( M \times N \times 3 \), comprising \( N \) chains of length \( M \) for each of the three quantities \( \alpha_1, \alpha_2 \) and \( \beta \).

Calculations for the case \( b = 2, \sigma = 0.2, \sigma_B = 0.2, \zeta_1 = 50e^{-b} \) and \( \zeta_2 = \zeta_1 + \sigma \) are performed in `r_exponential_example_2.m` and the results are published in `r_exponential_example_2.html`. Convergence indices along with the summary statistics based on the posterior distribution are displayed below.

Figure 6 shows the posterior distributions for \( \alpha_1, \alpha_2 \) and \( \beta \) estimated from the MCM and MCMC samples.
Figure 6: Posterior distributions estimated from MCM and MCMC samples for exponential example 2.
